Abstract of JP2003309856

PROBLEM TO BE SOLVED: To acquire a spectral image of an object with a motion.

SOLUTION: In a step S1, a high speed imaging section applies photoelectric conversion to an optical image of an object to produce a high speed image signal. In a step S2, a filter discrimination section analyzes the high speed image signal to detect a marking of a border area. In a step S3, a type of spectral filter placed before and after the marking is discriminated on the basis of a pattern of the detected marking, a corresponding filter discrimination signal is generated and outputted to a sort section. In a step S4, the sort section shares pixel data configuring the high speed image signal to built-in frame memories provided to each channel on the basis of the filter discrimination signal and outputs pixel data stored in the frame memories as a spectral image by eight channels every time a filter disk turns around. This invention is applicable to e.g. multi-spectral cameras.
